AWS S3 Event-Driven Automation Using AWS Lambda

Event-driven automation

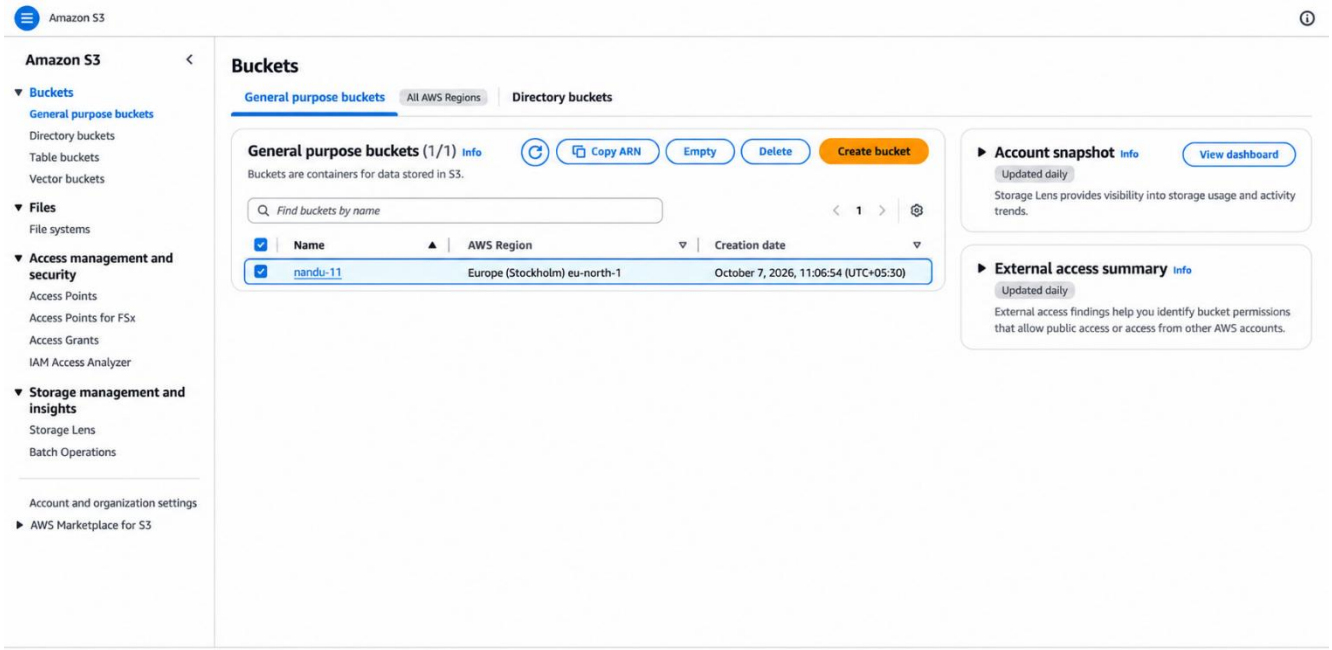

Event-driven automation means that when an event happens, AWS automatically triggers an action without you manually starting it.
For example, when someone uploads a file to an S3 bucket, AWS Lambda can automatically run code to process that file.

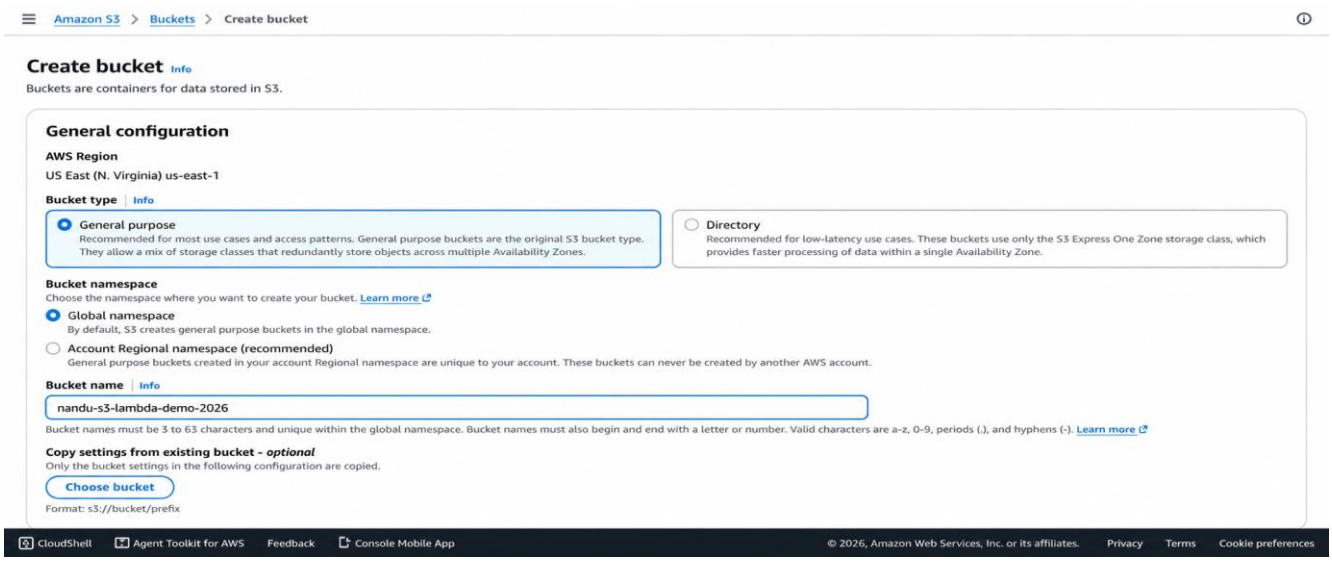

AWS service
Amazon S3: Stores files such as CSVs, images, and documents.
S3 Event Notification: Announces that an event, such as an object upload, occurred.
AWS Lambda: Runs your code in response to the event.
IAM role: Gives Lambda the permissions it needs, such as reading a file from S3.
CloudWatch Logs: Helps you inspect Lambda execution logs and troubleshoot errors.

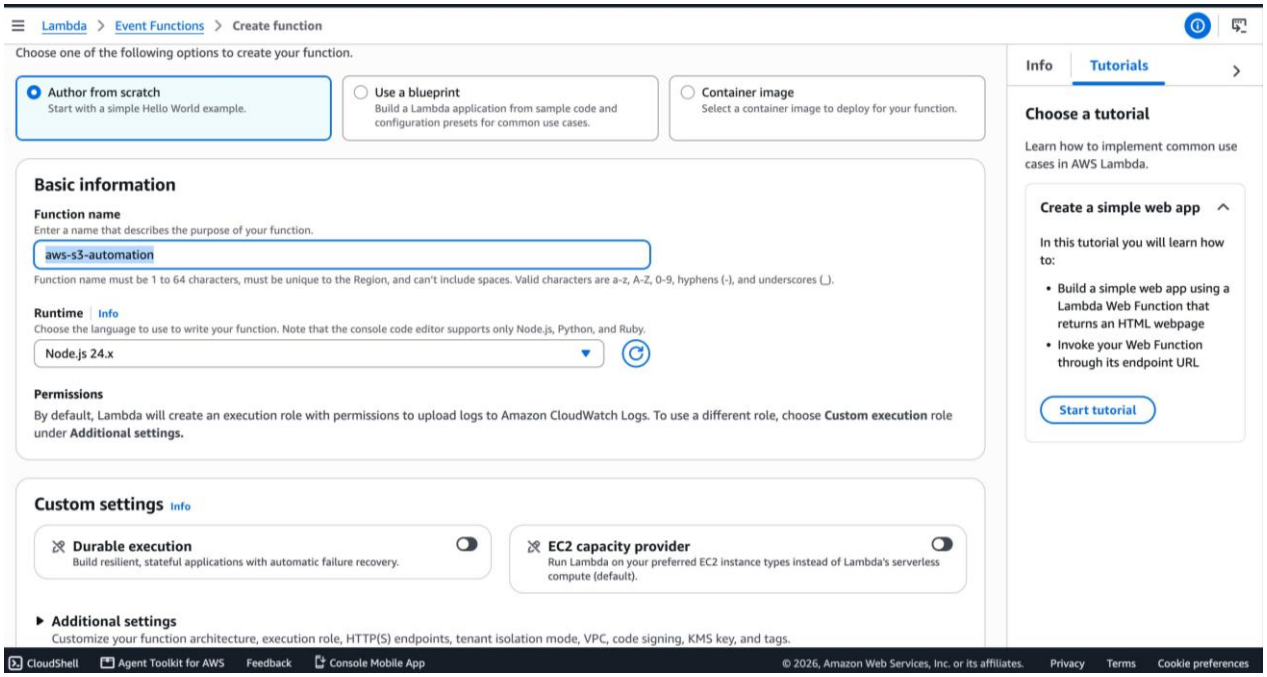

AWS documents this pattern as S3 invoking Lambda when an object is created; the function can then write details to CloudWatch Logs.

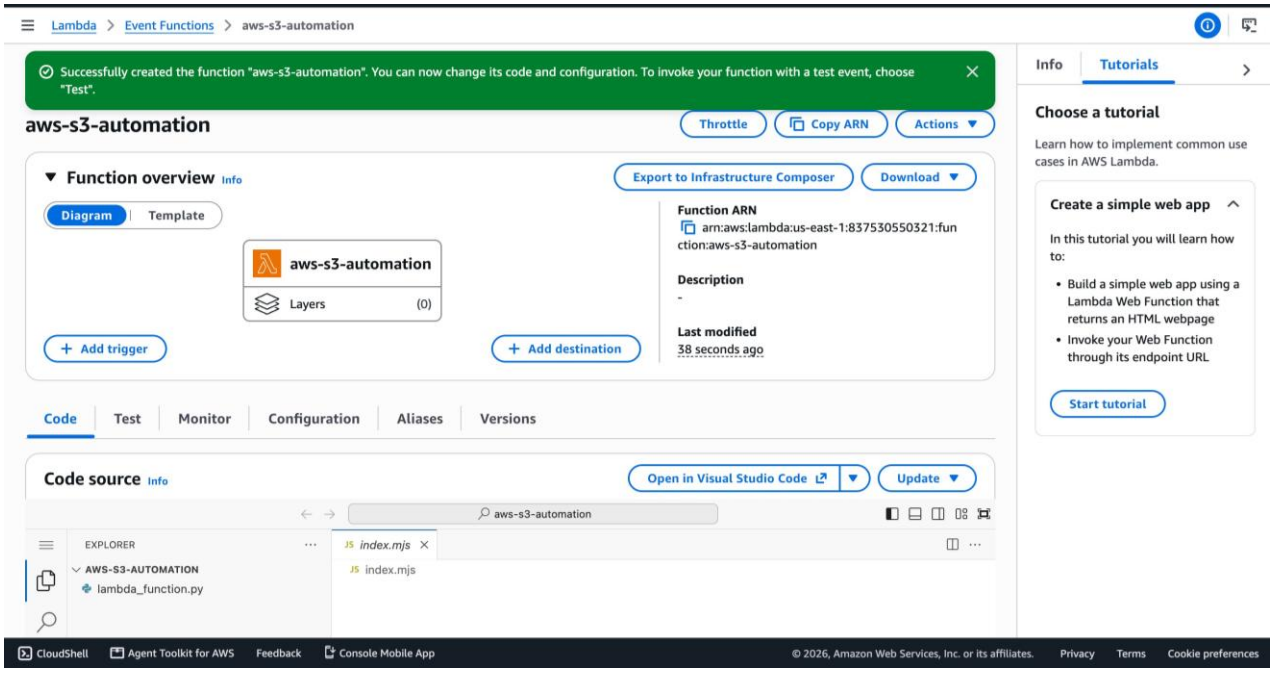

Create bucket.

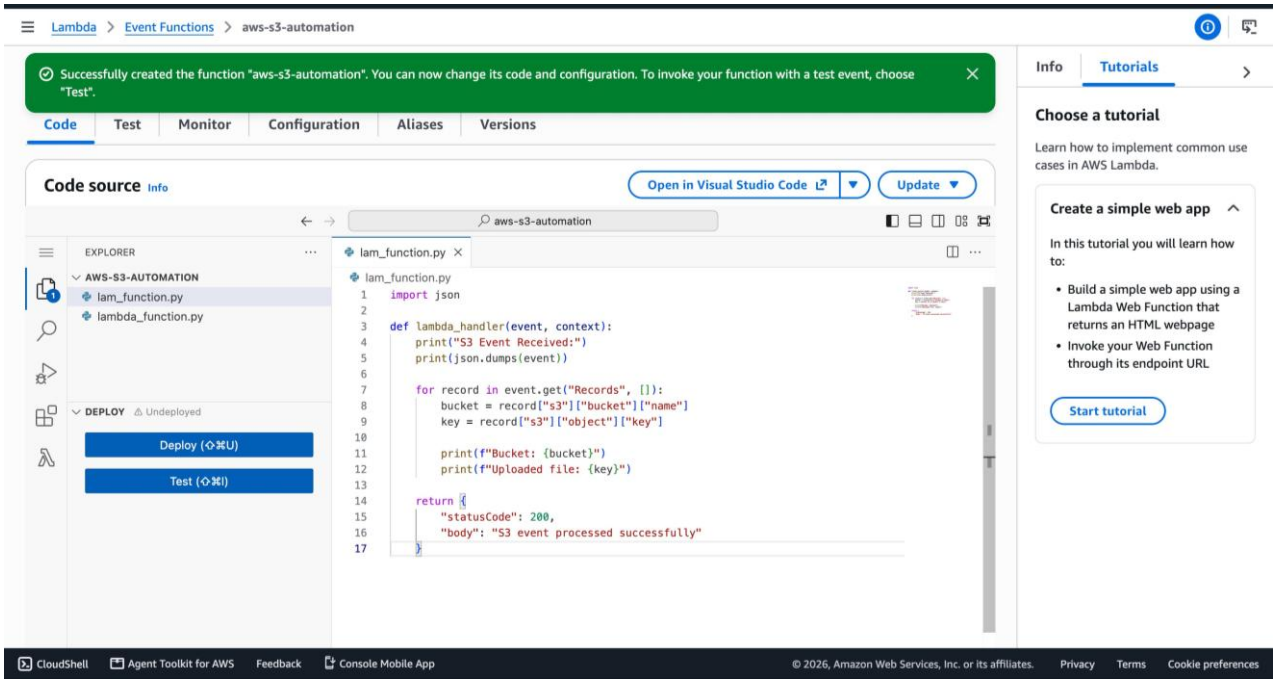

Create Event Function

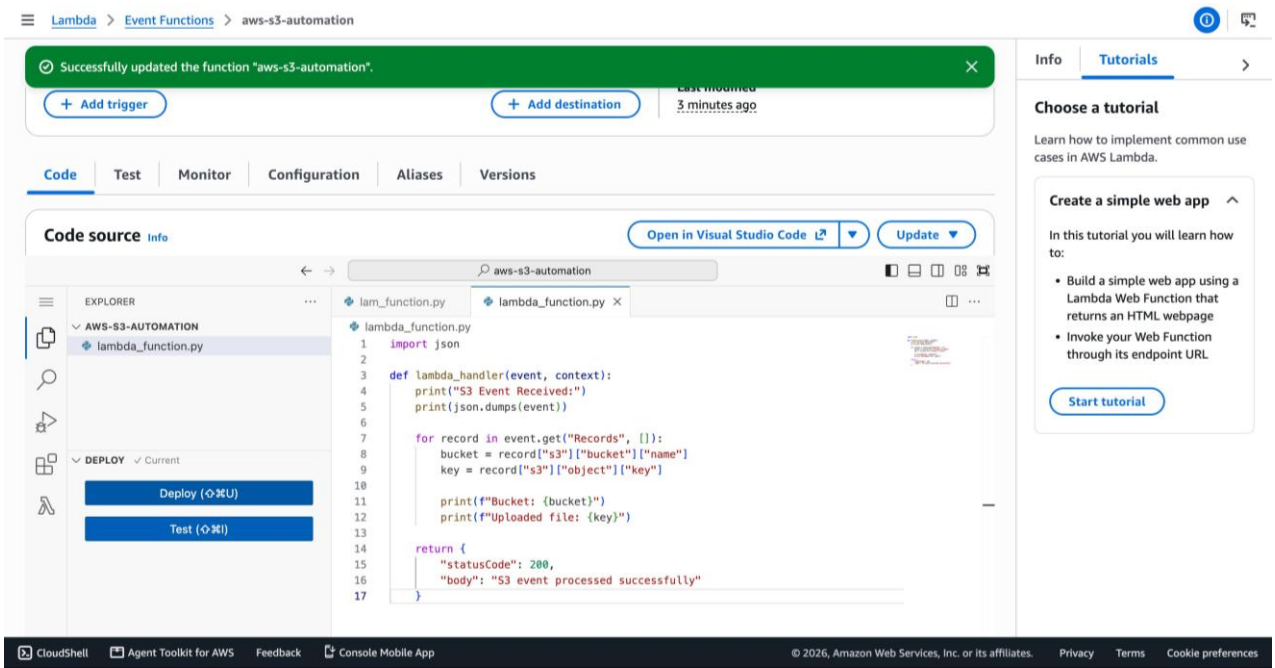

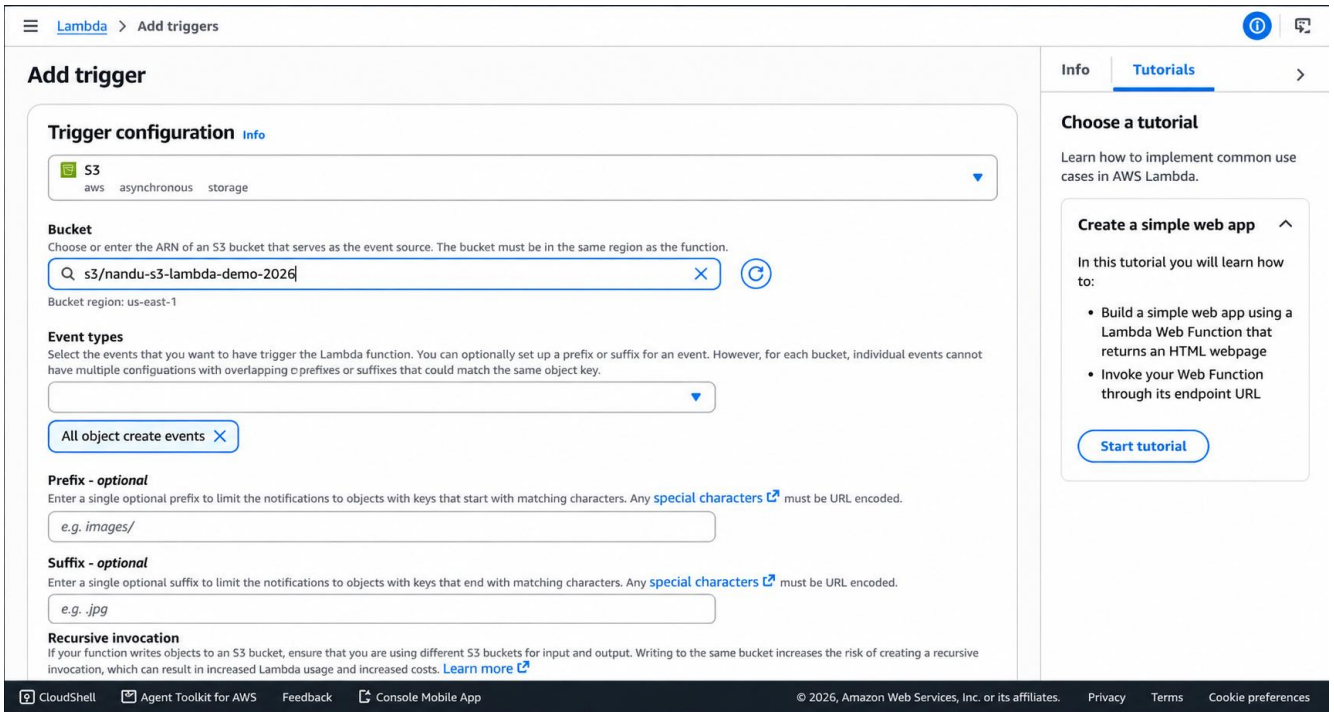

Add the Python code

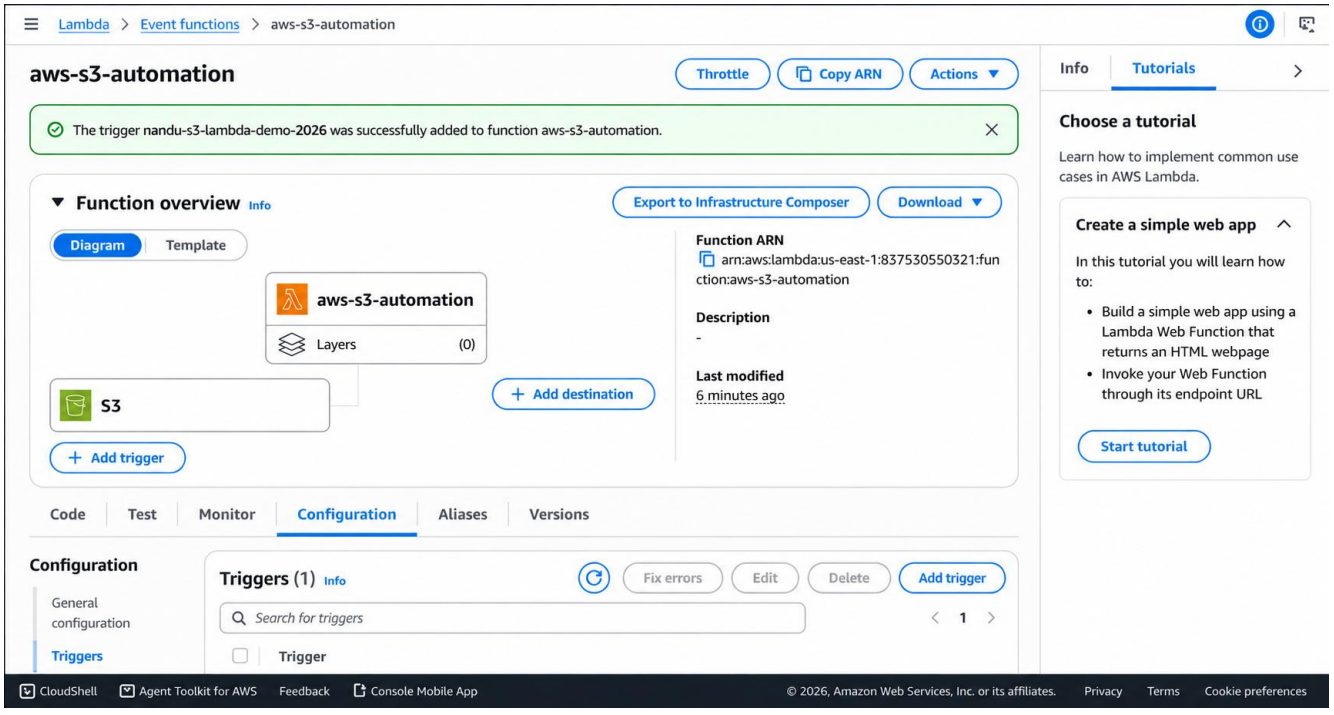

Click Deploy .

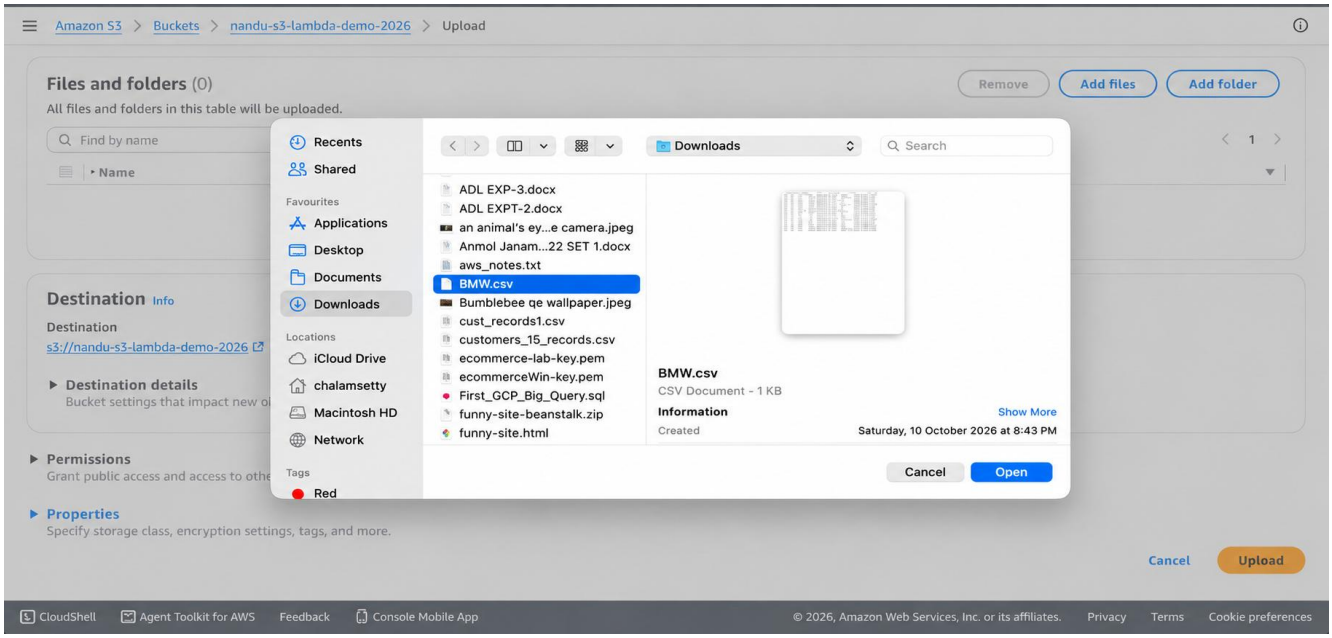

Connect S3 to Lambda

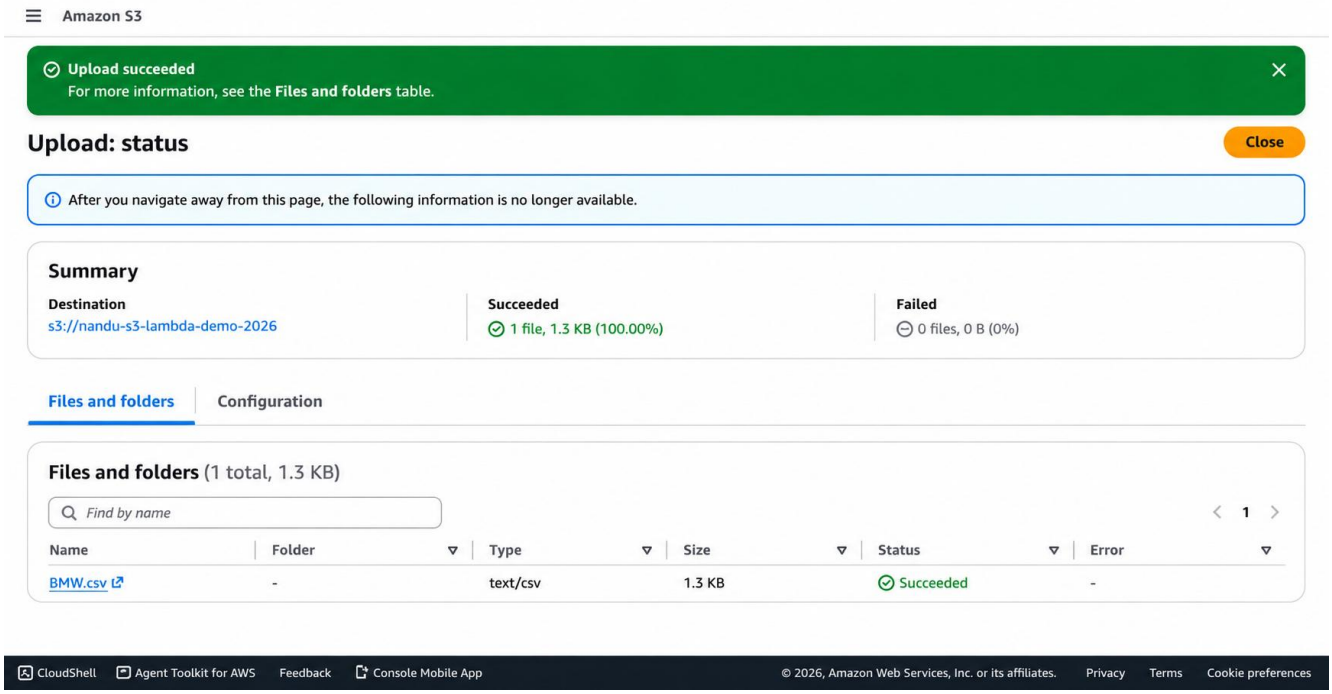

Upload a test file

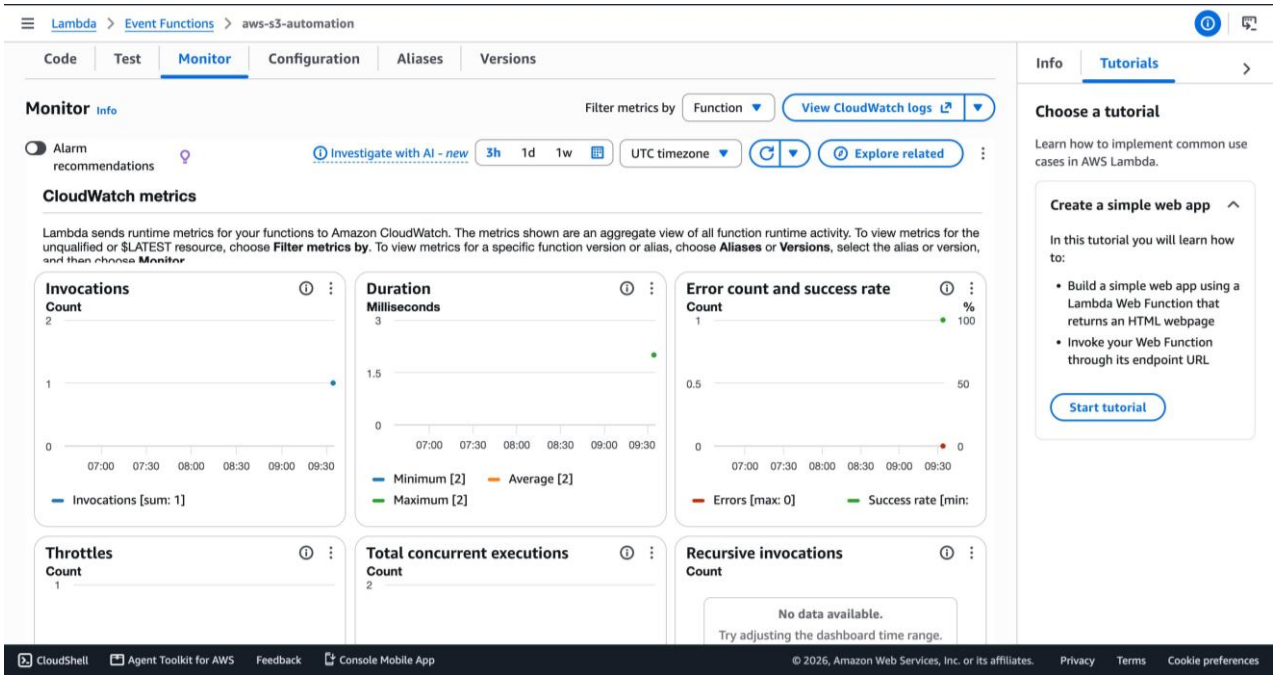

Open S3 → your practice bucket.
Click Upload → Add files.
Upload a file named BMW . `csv`.

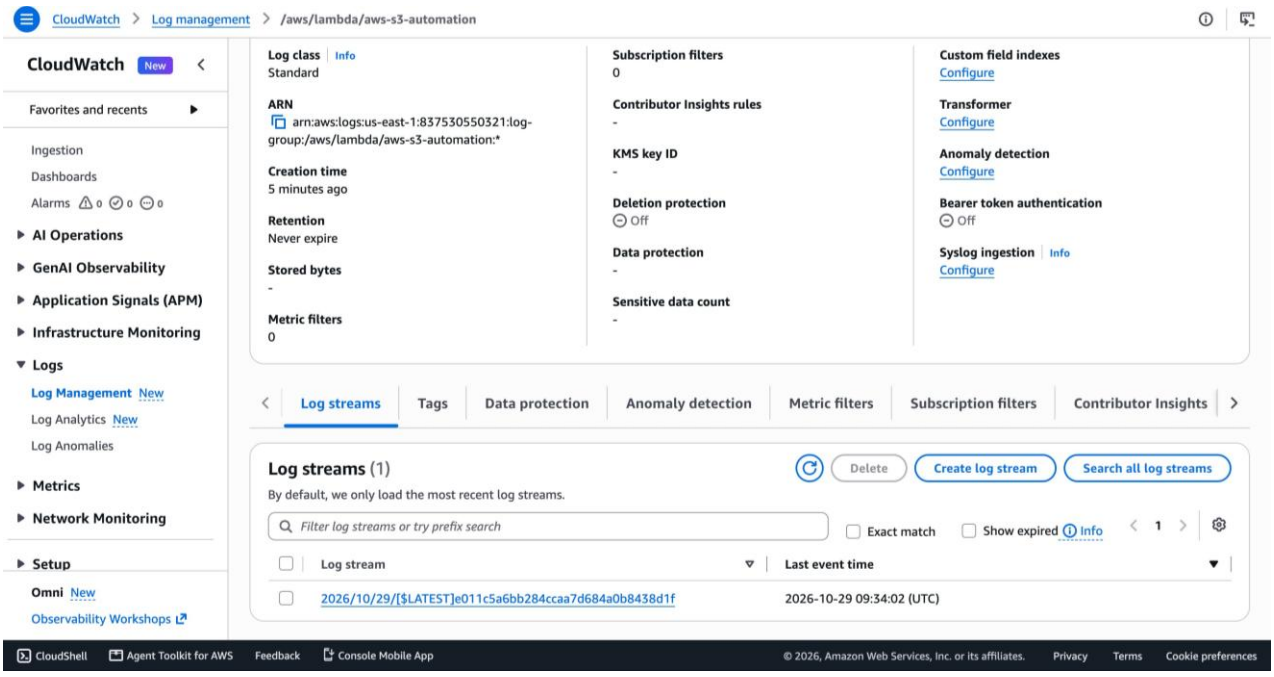

Lambda → s3-upload-automation.
Select the Monitor tab.

View CloudWatch logs.

FINAL OUTPUT
